1. About

JPim is an Open Source effort to implement a PIM library in Java that provides a reusable business object model for standard personal information and util packages that provide persistency and marshalling/unmarshalling capabilities.

The main focus to get started will be contacts and contact management; however if there is enough community interest, the next step is calendar data and calendar management and then anything else that qualifies within a reasonable understanding of "personal information".

The developed library should be accessible from any Java executeable context (i.e. Applet, Application, Web Application etc.).

2. Target Audience

Developers that want to build a PIM application, and do not like to reinvent the wheel all the time.
